Abstract:

Brain tumor is the most common kind of cancer, accounting for millions of fatalities worldwide. Early detection and treatment of new dangerous Brain tumor cases are critical to ensuring a low mortality rate as well as a high survival rate. The majority of relevant research has focused on machine learning-based algorithms, but they haven't been able to achieve the highest levels of accuracy and specificity. To address this issue, this work employs a deep learning based convolutional neural network (CNN) classification mechanism based on advanced deep learning. For effective identification of the location of Brain tumor, a k-means clustering based segmentation technique is first applied. Finally, CNN was constructed for Brain tumor classification with grey level co-occurrence matrix (GLCM) based Texture features, decimated wavelet Transform (DWT) based low level features, and Statistical Color features, respectively, to archive the system's maximum efficiency. As a result, the research findings can be utilized to classify benign and malignant based brain tumors. In comparison to state-of-the-art techniques, simulation study demonstrates that the suggested method provides better qualitative and quantitative analyses.

Abstract:

Generally remote sensing images are in hazy conditions such as fog, snow, thin cloud, dust etc., which results in contrast degradations in image. This work is based on the Dark Channel prior (DCP) to eliminate the haze effect on remote sensing images. In this model both natural images and remote sensing images Dehazingis possible. In the enhancement of satellite image properties several steps are involved, the first step is to identify whether the image is natural image or remote sensing image and restore it for the purpose of removing haze. By using air light values further, the iteration takes place with the help of DCP to remove dust and then the haze is eliminated by applying Iterative dehazing method for remote sensing image (IDERS) model. The output image obtained after Low light image enhancement (LIME) process is free from haze, brightness is enhanced. The simulation results shows that the performance of proposed method is improved as compared to the state of art approaches.

Abstract:

Video object detection plays the major role in variety applications including security, remote sensing and hyperspectral. Deep learning-based algorithms have made significant advances in video object recognition in recent years. The conventional machine learning applications are resulted in poor accuracy. In this article, a unified deep learning based convolutional neural network (DLCNN) is developed for composite multi object recognition in videos. To enhance composite object recognition, DLCNN analyses a composite item as a collection of background and adds part information into feature information. Correct component information may help forecast the shape and size of a feature data, which helps solve challenges caused by different forms and sizes of various objects. Finally, the DLCNN draws a bounding box to detected object by using the background features. Further, the simulation results shows that the performance of proposed method is improved as compared to the state of art approaches.

Abstract:

The ever-increasing numbers of new wireless technologies and services have resulted in increasing demand of smart wireless devices. The smart antennas in such devices should support all the required specifications so that these are compatible with different applications. Moreover, for realizing emerging wireless application such as cognitive radios, new requirements on the antenna are imposed. Novel antenna solutions which can easily reconfigure its operating parameter like frequency, bandwidth, pattern or polarization are required to support multiband, multimode and multi standard applications. Such antennas must support all these features in a single unit to produce small size, low cost, low profile integrated antenna which can be easily incorporated into the feature-rich applications. This paper deals with the design, simulation and fabrication of frequency reconfigurable antenna which have more than one reconfiguration features. In these we are adding extended parasitic elements to the Co-planar mono pole antenna for more than one resonant frequency. Co-planar waveguide fed polarization reconfigurable monopole antenna is used and PIN diodes are used as the switching device. The relevant design techniques, simulation results and fabrication details are presented. The integrated antenna structures need to be experimentally tested to validate the established parameters for antenna performance such as return loss, radiation pattern and gain.

Abstract:

A total of 412,000 persons are expected to be diagnosed with leukemia worldwide, with acute lymphoblastic leukemia accounting for around 12% of all cases. Thus, the early detection of leukemia can save millions of populations. This article mainly focusing on blood cell counting and detection of Leukemia using deep learning mechanisms. Initially, the images are preprocessed using median filters and segmented using RGB-Otsu's approach. Then, the features are extracted using scale-invariant feature transform (SIFT) and these features are applied to recurrent neural network (RNN) for classification. Finally, the proposed method resulted in superior performance as compared to the state of art machine learning approaches.

Abstract:
Different approaches for implementing a complex multiplier in pipelined FFT are considered and implemented to find an efficient one in this paper. The design is implemented in VHDL and design is synthesized on FPGA to know the performance. The design is implemented with a focus of reducing the resources used. Some approaches resulted in the reduced number of DSP blocks and others resulted in reduced number of LUTs. Analysis of Synthesis results is performed for different widths (bit lengths) of complex multiplier approaches.
